

Presentation for use with the textbook **Data Structures and Algorithms in Java, 6<sup>th</sup> edition**, by M. T. Goodrich, R. Tamassia, and M. H. Goldwasser, Wiley, 2014

# Stacks

# Abstract Data Types (ADTs)

- An abstract data type (ADT) is an abstraction of a data structure
- An ADT specifies:
  - Data stored
  - Operations on the data
  - Error conditions associated with operations
- Example: ADT modeling a simple stock trading system
  - The data stored are buy/sell orders
  - The operations supported are
    - ♦ order **buy**(stock, shares, price)
    - ♦ order **sell**(stock, shares, price)
    - ♦ void **cancel**(order)
  - Error conditions:
    - ♦ Buy/sell a nonexistent stock
    - ♦ Cancel a nonexistent order

# The Stack ADT

- The **Stack** ADT stores arbitrary objects
- Insertions and deletions follow the last-in first-out scheme
- Think of a spring-loaded plate dispenser
- Main stack operations:
  - **push**(object): inserts an element
  - object **pop**(): removes and returns the last inserted element
- Auxiliary stack operations:
  - object **top**(): returns the last inserted element without removing it
  - integer **size**(): returns the number of elements stored
  - boolean **isEmpty**(): indicates whether no elements are stored

# Stack Interface in Java

- ❑ Java interface corresponding to our Stack ADT
- ❑ Assumes null is returned from `top()` and `pop()` when stack is empty
- ❑ Different from the built-in Java class `java.util.Stack`

```
public interface Stack<E> {  
    int size();  
    boolean isEmpty();  
    E top();  
    void push(E element);  
    E pop();  
}
```

# Example

Method	Return Value	Stack Contents
push(5)	—	(5)
push(3)	—	(5, 3)
size()	2	(5, 3)
pop()	3	(5)
isEmpty()	false	(5)
pop()	5	()
isEmpty()	true	()
pop()	null	()
push(7)	—	(7)
push(9)	—	(7, 9)
top()	9	(7, 9)
push(4)	—	(7, 9, 4)
size()	3	(7, 9, 4)
pop()	4	(7, 9)
push(6)	—	(7, 9, 6)
push(8)	—	(7, 9, 6, 8)
pop()	8	(7, 9, 6)

# Exceptions vs. Returning Null

- ❑ Attempting the execution of an operation of an ADT may sometimes cause an error condition
  - ❑ Java supports a general abstraction for errors, called exception
  - ❑ An exception is said to be “thrown” by an operation that cannot be properly executed
- ❑ In our Stack ADT, we do not use exceptions
  - ❑ Instead, we allow operations pop and top to be performed even if the stack is empty
  - ❑ For an empty stack, pop and top simply return null

# Applications of Stacks

- Direct applications
  - Page-visited history in a Web browser
  - Undo sequence in a text editor
  - Chain of method calls in the Java Virtual Machine
- Indirect applications
  - Auxiliary data structure for algorithms
  - Component of other data structures

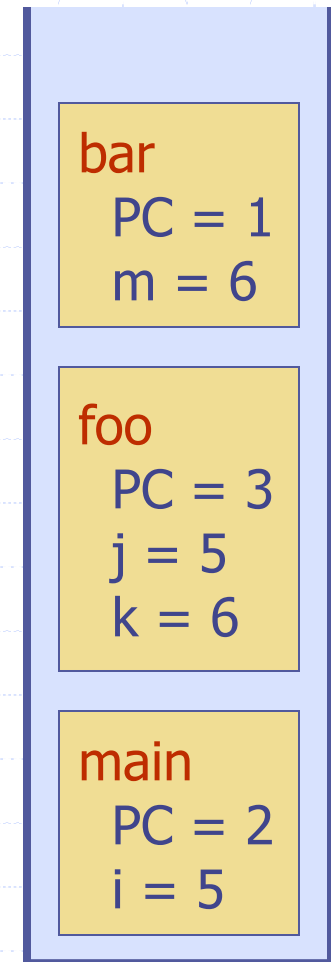

# Method Stack in the JVM

- ❑ The Java Virtual Machine (JVM) keeps track of the chain of active methods with a stack
- ❑ When a method is called, the JVM pushes on the stack a frame containing
  - Local variables and return value
  - Program counter, keeping track of the statement being executed
- ❑ When a method ends, its frame is popped from the stack and control is passed to the method on top of the stack
- ❑ Allows for **recursion**

```
main() {  
    int i = 5;  
    foo(i);  
}
```

```
foo(int j) {  
    int k;  
    k = j+1;  
    bar(k);  
}
```

```
bar(int m) {  
    ...  
}
```

# Array-based Stack

- A simple way of implementing the Stack ADT uses an array
- We add elements from left to right
- A variable keeps track of the index of the top element

**Algorithm** *size()*  
**return**  $t + 1$

**Algorithm** *pop()*  
**if** *isEmpty()* **then**  
    **return** null  
**else**  
     $t \leftarrow t - 1$   
    **return**  $S[t + 1]$

# Array-based Stack (cont.)

- The array storing the stack elements may become full
- A push operation will then throw a **FullStackException**
  - Limitation of the array-based implementation
  - Not intrinsic to the Stack ADT

```
Algorithm push(o)  
  if  $t = S.length - 1$  then  
    throw IllegalStateException  
  else  
     $t \leftarrow t + 1$   
     $S[t] \leftarrow o$ 
```

# Performance and Limitations

## □ Performance

- Let  $n$  be the number of elements in the stack
- The space used is  $O(n)$
- Each operation runs in time  $O(1)$

## □ Limitations

- The maximum size of the stack must be defined a priori and cannot be changed
- Trying to push a new element into a full stack causes an implementation-specific exception

# Array-based Stack in Java

```
public class ArrayStack<E>
    implements Stack<E> {

    // holds the stack elements
    private E[] S;

    // index to top element
    private int top = -1;

    // constructor
    public ArrayStack(int capacity) {
        S = (E[]) new Object[capacity];
    }
}
```

```
public E pop() {
    if isEmpty()
        return null;
    E temp = S[top];
    // facilitate garbage collection:
    S[top] = null;
    top = top - 1;
    return temp;
}

... (other methods of Stack interface)
```

# Example Use in Java

```
public class Tester {  
    // ... other methods  
    public intReverse(Integer a[]) {  
        Stack<Integer> s;  
        s = new  
        ArrayStack<Integer>();  
        ... (code to reverse array a) ...  
    }
```

```
public floatReverse(Float f[]) {  
    Stack<Float> s;  
    s = new ArrayStack<Float>();  
    ... (code to reverse array f) ...  
}
```

# Parentheses Matching

- Each “(”, “{”, or “[” must be paired with a matching “)”, “}”, or “]”
  - correct: ( )(( )){([ ( ))}
  - correct: ((( ))(( )){([ ( ))}
  - incorrect: )(( )){([ ( ))}
  - incorrect: ({ [ ]})
  - incorrect: (

# Parenthesis Matching (Java)

```
public static boolean isMatched(String expression) {  
    final String opening = "{["; // opening delimiters  
    final String closing = "}]"; // respective closing delimiters  
    Stack<Character> buffer = new LinkedStack<>( );  
    for (char c : expression.toCharArray( )) {  
        if (opening.indexOf(c) != -1) // this is a left delimiter  
            buffer.push(c);  
        else if (closing.indexOf(c) != -1) { // this is a right delimiter  
            if (buffer.isEmpty( )) // nothing to match with  
                return false;  
            if (closing.indexOf(c) != opening.indexOf(buffer.pop( )))  
                return false; // mismatched delimiter  
        }  
    }  
    return buffer.isEmpty( ); // were all opening delimiters matched?  
}
```

# HTML Tag Matching

- For fully-correct HTML, each `<name>` should pair with a matching `</name>`

```
<body>
<center>
<h1> The Little Boat </h1>
</center>
<p> The storm tossed the little
boat like a cheap sneaker in an
old washing machine. The three
drunken fishermen were used to
such treatment, of course, but
not the tree salesman, who even as
a stowaway now felt that he
had overpaid for the voyage. </p>
<ol>
<li> Will the salesman die? </li>
<li> What color is the boat? </li>
<li> And what about Naomi? </li>
</ol>
</body>
```

## The Little Boat

The storm tossed the little boat like a cheap sneaker in an old washing machine. The three drunken fishermen were used to such treatment, of course, but not the tree salesman, who even as a stowaway now felt that he had overpaid for the voyage.

1. Will the salesman die?
2. What color is the boat?
3. And what about Naomi?

# HTML Tag Matching (Java)

```
public static boolean isHTMLMatched(String html) {
    Stack<String> buffer = new LinkedStack<>( );
    int j = html.indexOf('<'); // find first '<' character (if any)
    while (j != -1) {
        int k = html.indexOf('>', j+1); // find next '>' character
        if (k == -1)
            return false; // invalid tag
        String tag = html.substring(j+1, k); // strip away < >
        if (!tag.startsWith("/")) // this is an opening tag
            buffer.push(tag);
        else { // this is a closing tag
            if (buffer.isEmpty( ))
                return false; // no tag to match
            if (!tag.substring(1).equals(buffer.pop( )))
                return false; // mismatched tag
        }
        j = html.indexOf('<', k+1); // find next '<' character (if any)
    }
    return buffer.isEmpty( ); // were all opening tags matched?
}
```

# Evaluating Arithmetic Expressions

Slide by Matt Stallmann  
included with permission.

$$14 - 3 * 2 + 7 = (14 - (3 * 2)) + 7$$

Operator precedence

\* has precedence over +/−

Associativity

operators of the same precedence group  
evaluated from left to right

Example:  $(x - y) + z$  rather than  $x - (y + z)$

**Idea:** push each operator on the stack, but first pop and perform higher and *equal* precedence operations.

# Algorithm for Evaluating Expressions

Two stacks:

- opStk holds operators
- valStk holds values
- Use \$ as special “end of input” token with lowest precedence

Algorithm **doOp()**

```
x ← valStk.pop();  
y ← valStk.pop();  
op ← opStk.pop();  
valStk.push( y op x )
```

Algorithm **repeatOps( refOp )**:

```
while ( valStk.size() > 1 ∧  
        prec(refOp) ≤  
        prec(opStk.top())  
        doOp()
```

Algorithm **EvalExp()**

Input: a stream of tokens representing  
an arithmetic expression (with  
numbers)

Output: the value of the expression

**while** there's another token z

**if** isNumber(z) **then**

valStk.push(z)

**else**

repeatOps(z);

opStk.push(z)

repeatOps(\$);

**return** valStk.top()

$$14 \leq 4 - 3 * 2 + 7$$

# Computing Spans (not in book)

- Using a stack as an auxiliary data structure in an algorithm
- Given an array  $X$ , the **span**  $S[i]$  of  $X[i]$  is the maximum number of consecutive elements  $X[j]$  immediately preceding  $X[i]$  and such that  $X[j] \leq X[i]$
- Spans have applications to financial analysis
  - E.g., stock at 52-week high

$X$	6	3	4	5	2
$S$	1	1	2	3	1

# Quadratic Algorithm

**Algorithm** *spans1*( $X, n$ )

**Input** array  $X$  of  $n$  integers

**Output** array  $S$  of spans of  $X$

$S \leftarrow$  new array of  $n$  integers

**for**  $i \leftarrow 0$  **to**  $n - 1$  **do**

$s \leftarrow 1$

**while**  $s \leq i \wedge X[i - s] \leq X[i]$

$s \leftarrow s + 1$

$S[i] \leftarrow s$

**return**  $S$

#

$n$

$n$

$n$

$1 + 2 + \dots + (n - 1)$

$1 + 2 + \dots + (n - 1)$

$n$

1

◆ Algorithm *spans1* runs in  $O(n^2)$  time

# Computing Spans with a Stack

- We keep in a stack the indices of the elements visible when “looking back”
- We scan the array from left to right
  - Let  $i$  be the current index
  - We pop indices from the stack until we find index  $j$  such that  $X[i] < X[j]$
  - We set  $S[i] \leftarrow i - j$
  - We push  $i$  onto the stack

# Linear Time Algorithm

- Each index of the array
  - Is pushed into the stack exactly one
  - Is popped from the stack at most once
- The statements in the while-loop are executed at most  $n$  times
- Algorithm *spans2* runs in  $O(n)$  time

<b>Algorithm</b> <i>spans2</i> ( $X, n$ )	#
$S \leftarrow$ new array of $n$ integers	$n$
$A \leftarrow$ new empty stack	1
<b>for</b> $i \leftarrow 0$ <b>to</b> $n - 1$ <b>do</b>	$n$
<b>while</b> $(\neg A.isEmpty() \wedge$	
$X[A.top()] \leq X[i])$ <b>do</b>	$n$
$A.pop()$	$n$
<b>if</b> $A.isEmpty()$ <b>then</b>	$n$
$S[i] \leftarrow i + 1$	$n$
<b>else</b>	
$S[i] \leftarrow i - A.top()$	$n$
$A.push(i)$	$n$
<b>return</b> $S$	1
